Dear all

As discussed in class, Assignment 2 is attached.

Problem 2 (a).

Take a language which is a subset of C (you have taken in Assign 1 (a)). Define CFG grammar for the language. Generate LL(1) and SLR parsing tables.

Take strings of tokens generated by Assignment 1(a). Perform parsing both top-down and bottom-up for the string. Also, your parser should have error detection capability. Further, the parser should also take arbitrary CFGs and generate LL(1) and SLR tables; conflicts should also be marked.

The problem defined above describes ONLY the basic requirements. You are free to implement in your own way for efficiency in implementation, however, you must remember that computation power should not be more than that required by LL(1) or SLR (for respective cases). Extra credits will be given for "efficiency in implementation" and good display of parsing tables and parsing steps (stack etc.)!!!!

-----  
Problem1 (b).

Implement a Parsing analyzer using tools for the language "Cool". Details of the assignment are attached as a .pdf file.
